Recurrent Language Modeling

Let's delve a bit deeper into a recurrent network and language modeling with it.

Recurrent Language Model

Example (the, cat, is, eating)

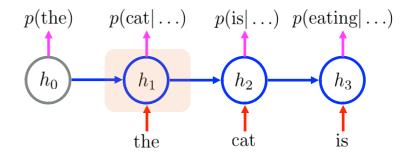

Read, Update and Predict

Transition Function $f(h_{t-1}, x_{t-1})$

- Inputs
 - i. Previous word $-1 \in \{1, 2, \dots, |V|\}$
 - ii. Previous stat $e_{-1} \in \mathbb{R}^d$
- Parameters
 - i. Input weight matrix $\mathbb{R}^{|V| imes d}$
 - ii. Transition weight matei $\mathbb{R}^{d \times d}$
 - iii. Bias vector $\in \mathbb{R}^d$
- Naïve Transition Function

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

Transition Function $f(h_{t-1}, x_{t-1})$

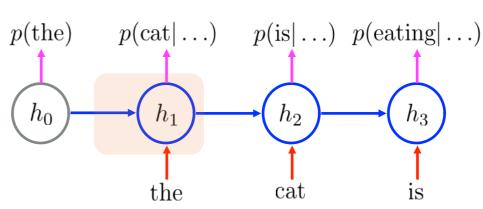

Naïve Transition Function

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

Element-wise nonlinear transformation

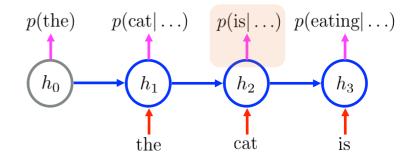

Linear transformation of previous state

Trainable word vector

Readout Function
$$= w|x_{< t}| = g_w(h_t)$$

- Inputs
 - i. Current state $\in \mathbb{R}^d$
- Parameters
 - i. Readout weight ma $\operatorname{Res}^{|V| \times d}$
 - ii. Bias vector $\in \mathbb{R}^{|V|}$

Softmax Readout

$$p(x_t = w | x_{< t}) = g_w(h_t) = \frac{\exp(R[w]^\top h_t + c_w)}{\sum_{i=1}^{|V|} \exp(R[i]^\top h_t + c_i)}$$

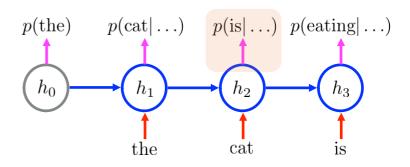

Readout Function $x_t = w|x_{< t} = g_w(h_t)$

$$p(x_t = w | x_{< t}) = g_w(h_t) = \frac{\exp(R[w]^{\top} h_t + c_w)}{\sum_{i=1}^{|\mathcal{N}|} \exp(R[i]^{\top} h_t + c_i)}$$

Exponentiation

Compatibility
between a
trainable word
vector and
the hidden state

Normalization

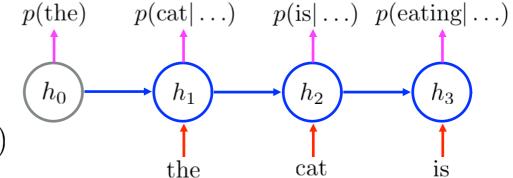

Training a Recurrent Language Model

Log-probability of one training sentence

$$\log p(x_1^n, x_2^n, \dots, x_{T^n}^n) = \sum_{t=1}^{T^n} \log p(x_t^n | x_1^n, \dots, x_{t-1}^n)$$

- Training set $= \{X^1, X^2, \dots, X^N\}$
- Log-likelihood Functional

$$\mathcal{L}(\theta, D) = \frac{1}{N} \sum_{n=1}^{N} \sum_{t=1}^{T^n} \log p(x_t^n | x_1^n, \dots, x_{t-1}^n)$$

 $Minimize \mathcal{L}(\theta, D)$

!!

Minibatch Stochastic Gradient Descent

Building a minibatch is not trivial due to length

1. Padding and Masking: suitable for GPU's, but wasteful $\sum_{l} \max_{x} l(X^{n'}) - l(X^n)$

Wactad computation "-1,,"				
Sentence 1		0's		
Sentence 2		0's		
Sentence 3				
Sentence 4		0's		

Minibatch Stochastic Gradient Descent

Descent, and Masking; suitable for GPU's, but wasteful $\sum_{n'=1}^{max} l(X^{n'}) - l(X^n)$

•	Wasted computation:				
	Sentence 1		0's		
	Sentence 2		0's		
	Sentence 3				
	Sentence 4		0's		

- 2. Smarter Padding and Masking: minimize the waste
 - Ensure that the length differences are minimal.
 - Sort the sentences and sequentially build a

Sentence 1		0's	
Sentence 2		0's	
Sentence 3		0's	
Sentence 4			

Minibatch Stochastic Gradient Descenter Padding and Masking: minimize the waste

Sentence 1		0's	
Sentence 2		0's	
Sentence 3		0's	
Sentence 4			

- 3. Smarter Padding and Smarter Stopping: *toward* zero waste
 - Drop a finished sentence from a minibatch
 - •__ Not as flexible...

Sentence 1	→ ()'s
Sentence 2	- ►	0's
Sentence 3		— 0 ′s ▶
Sentence 4		

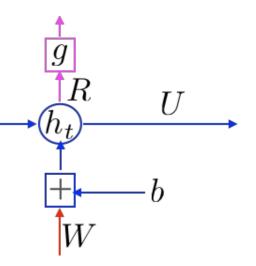

How do we comp(x)

• Decompose the per-sample cost into per-step cost

functions
$$\nabla \mathcal{L}(\theta, X) = \sum_{t=1}^{T} \nabla \log p(x_t | x_{< t}, \theta)$$

- Compute per-step cost function from time
 - 1. Cost derivative $p(x_t|x_{< t})/\partial g$
 - 2. Gradient w. $\Re x \times \partial g / \partial R$
 - 3. Gradient w. $h_t \times \partial g/\partial h_t + \partial h_{t+1}/\partial h_t \log p(x_t|x_{< t})$
 - 4. Gradient w. ηt . $\times \partial h_t/\partial U$
 - 5. Gradient w.rkt. Which $\partial h_t / \partial b \times \partial h_t / \partial W$
 - 6. Accumulate the gradient and 1

Note: I'm abusing math a lot here!!

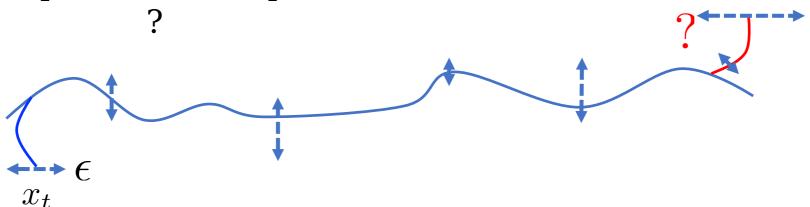

Intuitively, what's happening here?

1. Measure the influence of the past on the future

$$\frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial h_t} = \frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial g} \frac{\partial g}{\partial h_{t+n}} \frac{\partial h_{t+n}}{\partial h_{t+n-1}} \cdots \frac{\partial h_{t+1}}{\partial h_t} \frac{\partial h_t}{\partial x_t}$$

2. If I perturb the input at , how does p(t) affect t+n

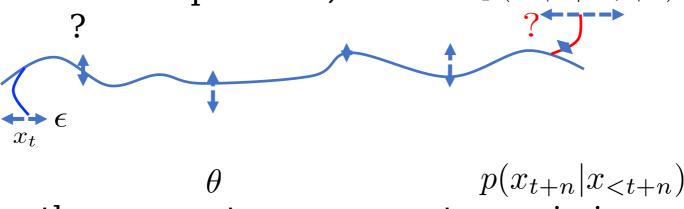

Intuitively, what's happening here?

1. Measure the influence of the past on the future

$$\frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial h_t} = \frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial g} \frac{\partial g}{\partial h_{t+n}} \frac{\partial h_{t+n}}{\partial h_{t+n-1}} \cdots \frac{\partial h_{t+1}}{\partial h_t} \frac{\partial h_t}{\partial x_t}$$

2. If I perturb the input at , how does $(it_{t-a}ffee_{t+n})$

3. Change the parameters so as to maximize

Intuitively, what's happening here?

1. Measure the influence of the past on the future

$$\frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial h_t} = \frac{\partial \log p(x_{t+n}|x_{< t+n})}{\partial g} \frac{\partial g}{\partial h_{t+n}} \frac{\partial h_{t+n}}{\partial h_{t+n-1}} \cdots \frac{\partial h_{t+1}}{\partial h_t}$$

2. With a naïve transition function

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

We get
$$\frac{\partial J_{t+n}}{\partial h_t} = \frac{\partial J_{t+n}}{\partial g} \frac{\partial g}{\partial h_{t+N}} \prod_{n=1}^N U^{\top} \operatorname{diag} \left(\frac{\partial \tanh(a_{t+n})}{\partial a_{t+n}} \right)$$

Problematic!

- Bengio et al. (1994)

Gradient either vanishes or explodes

• What happens
$$\frac{\partial J_{t+n}}{\partial h_t} = \frac{\partial J_{t+n}}{\partial g} \frac{\frac{\partial J_{t+n}}{\partial g}}{\frac{\partial J_{t+n}}{\partial h_{t+N}}} \prod_{n=1}^{(2013)} U^{\top} \operatorname{diag} \left(\frac{\partial \tanh(a_{t+n})}{\partial a_{t+n}} \right)$$

1. The gradient *likely* explodes if

$$e_{\max} \ge \frac{1}{\max \tanh'(x)} = 1$$

2. The gradient *likely* vanishes if

$$e_{\max} < \frac{1}{\max \tanh'(x)} = 1$$

 e_{\max} : largest eigenvalue of

Let the (norm of the) gradient explode!

 "when gradients explode so does the curvature along v, leading to a wall in the error surface"

- Simple solution: Gradient Clipping
 - 1. Norm clipping $|\nabla \nabla| = |\nabla \nabla| = c$ $|\nabla \nabla| = c$ $|\nabla \nabla| = c$ $|\nabla \nabla| = c$

2. Element-wise clipping $\nabla_i \leftarrow \min(c, \nabla_i)$, for all $i \in \{1, \dots, \dim \nabla\}$

Pascanu et al. (2013)

Vanishing gradient is super-problematic

- We cannot tell whether
 - 1. no long-term dependency between t and t+n in data, or
 - 2. wrong configuration of parameters: $\max \tanh'(x)$

• We only observe
$$\left\| \frac{\partial h_{t+N}}{\partial h_t} \right\| = \left\| \prod_{n=1}^N U^\top \operatorname{diag} \left(\frac{\partial \tanh(a_{t+n})}{\partial a_{t+n}} \right) \right\| \to 0$$

Vanishing gradient is super-problematic

- Let's just say there is such a long-term dependency. Then,
 - "we ... force the network to incre $\frac{\partial h_t}{\partial h_t}$ the norm of the expense of larger errors"

 Pascanu et al. (2013)
- This can be don

$$\sum_{t=1}^{T} \left(1 - \frac{\left\| \frac{\partial \tilde{C}}{\partial \mathbf{h}_{t+1}} \frac{\partial \mathbf{h}_{t+1}}{\partial \mathbf{h}_{t}} \right\|}{\left\| \frac{\partial \tilde{C}}{\partial \mathbf{h}_{t+1}} \right\|} \right)^{2}$$

 This doesn't seem like a great nor easy way to deal with the vanishing gradient.

• Perhaps, the problem is with the naïve transition function

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

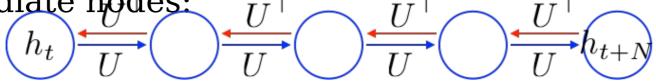

• With it, the temporal derivative is

$$\frac{\partial h_{t+1}}{\partial h_t} = U^{\top} \frac{\partial \tanh(a)}{\partial a}$$

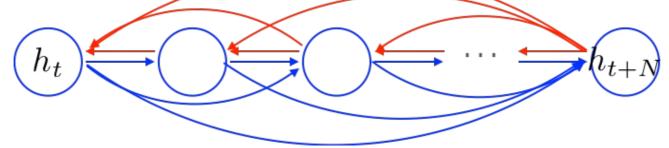

• It implies that the error must backpropagate through all the intermediate nodes:

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

It implies that the error must backpropagate through all the intermediate nodes: $U^{\top} \cap U^{\top} \cap U^{\top}$

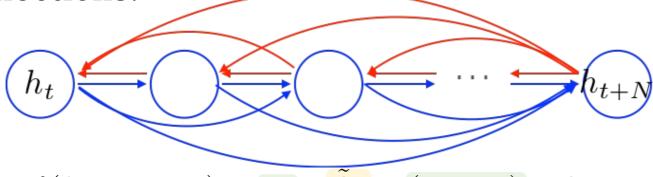

Perhaps we can create shortcut connections.

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

• Perhaps we can create *adaptive* shortcut connections.

$$f(h_{t-1}, x_{t-1}) = u_t \odot h_t + (1 - u_t) \odot h_{t-1}$$

$$\tilde{h}_t = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

- Candidate $UpdateW_u[x_{t-1}] + U_uh_{t-1} + b_u$
- Update gate

$$f(h_{t-1}, x_{t-1}) = \tanh(W[x_{t-1}] + Uh_{t-1} + b)$$

 We also let the network prune unnecessary shortcuts adaptively.

$$h_t$$
 h_{t+N}

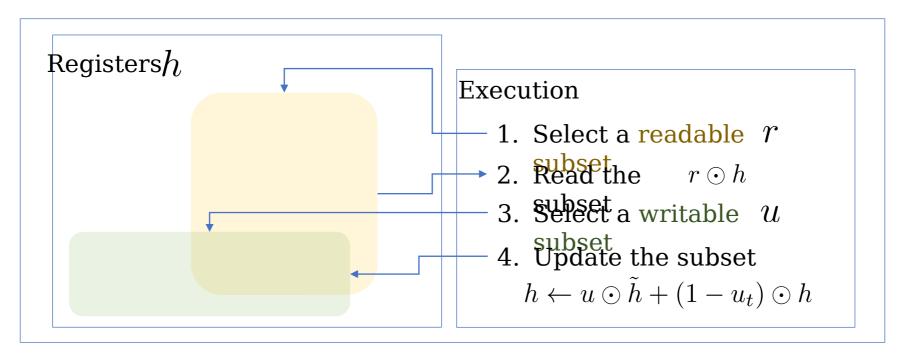

$$f(h_{t-1}, x_{t-1}) = u_t \odot \tilde{h}_t + (1 - u_t) \odot h_{t-1}$$
$$\tilde{h}_t = \tanh(W x_{t-1} + U(r_t \odot h_{t-1}) + b)$$

- Candidate $\mathbf{v}_t \mathbf{U} \mathbf{p} \mathbf{d} \mathbf{d} \mathbf{W}_r x_{t-1} + U_r h_{t-1} + b_r$
- Reset gate_{u_t} = $\sigma(W_u[x_{t-1}] + U_u h_{t-1} + b_u)$
- Update gate

tanh-RNN vs CPU

GRU vs CPU

Clearly gated recurrent units* are much more realistic.

* By gated recurrent units, I refer to both

Machine Translation: a Natural Extension of Neural Language Modeling

You have already learned how to build it.

Machine Translation

- Input: a sentence written in a sourdes language
- Output: a corresponding sentence in a target language
- Problem statement:
 - Supervised learning: given the input sentence, output its translation
 - Compute the conditional distribution over all possible translation given the input

• We have already learned every necessary ingredient for building a full neural machine translation system.

Token Representation – One-hot Vectors

- 1. Build source and target vocabularies of unique tokens
 - For each of source and target languages,
 - 1. Tokenize: separate punctuations, normalize punctuations, ... e.g., "I'm going" => ("I", "'m", "going"), replace ', ', `, into "`", ... use Spacy.io, NLTK or Moses' tokenizer.
 - 2. Subword segmentation: segment each token into a sequence of subwords e.g., "going" => ("go", "ing"), use BPE [Sennrich et al., 2015]
 - 3. Collect all unique subwords, sort them by their frequencies (descending) and assign indices.
- 2. Transform each subword token into a corresponding one-hot vector.*

Encoder - Source Sentence Representation

- Encode the source sentence into a set of sentence representation vectors
 - # of e_{η} code d_{τ} vectors is proportional to the source sentence length: often same.
 - Recurrent networks have been widely used [Cho et al., 2014; Sutskever et al., 2014], but CNN [Gehring et al., 2017; Kalchbrenner&Blunsom, 2013] and self-attention [Vaswani et al., 2017] are used increasingly more often. See Lecture 2 for details.
- We do not want to collapse them into a single vector.
 - Collapsing often corresponds to information loss.
 - Increasingly more difficult to encode the entire source

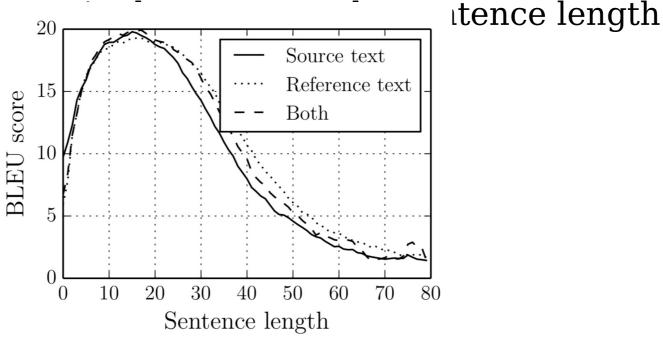

Encoder - Source Sentence

Representation
• Encode the source sentence into a set of sentence representation vectors

We do not want to collapse them into a single vector.

Increasingly more difficult to encode the entire source

sentence in increases [C

Encoder - Source Sentence

- Representation
 Encode the source sentence into a set of sentence representation vectors
- We do not want to collapse them into a single vector.
 - Increasingly more difficult to encode the entire source sentence into a single vector, as the sentence length increases [Cho et al., 2014b].
 - When collapsed, the system fails to translate a long sentence correctly.
 - **Source**: An admitting privilege is the right of a doctor to admit a patient to a hospital or a medical centre to carry out a diagnosis or a procedure, based on his status as a health care worker at a hospital.
 - When collapsed: Un privilège d'admission est le droit d'un médecin de reconnaître un patient à l'hôpital ou un centre médical <u>d'un</u> diagnostic ou de prendre un diagnostic en fonction de son état de santé.
 - The system translates reasonable up to a certain point but

Decoder - Language Modelling

- Autoregressive Language modelling with an infinite context $n\rightarrow\infty$
 - Larger context is necessary to generate a coherent sentence.
 - Semantics could be largely provided by the source sentence, but syntactic properties need to be handled by the language model directly.
 - Recurrent networks, self-attention and (dilated) convolutional networks
 - Causal structure must be followed.
 - See Lecture 3.
- Conditional Language modelling
 - The context based on which the next token is predicted is **two-fold**

Decoder – Conditional Language Modelling

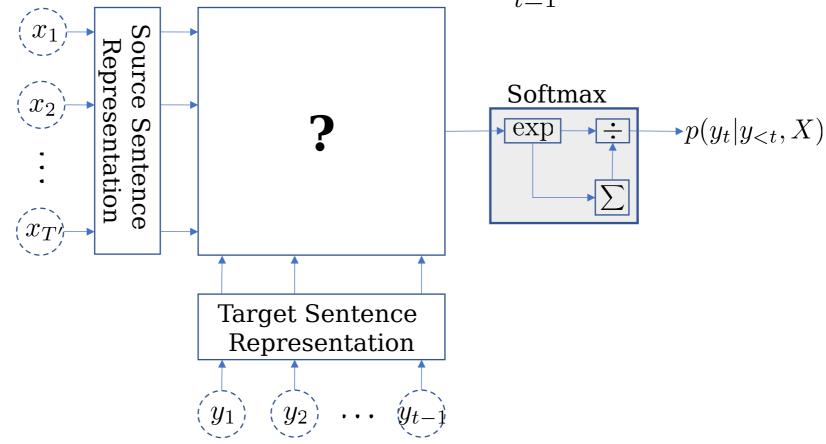

- Conditional Language modelling
 - The context based on which the next token is predicted is **two-fold**. \underline{T}

two-fold.
$$p(Y|X) = \prod_{t=1}^{T} p(y_t|y_{< t}, X)$$

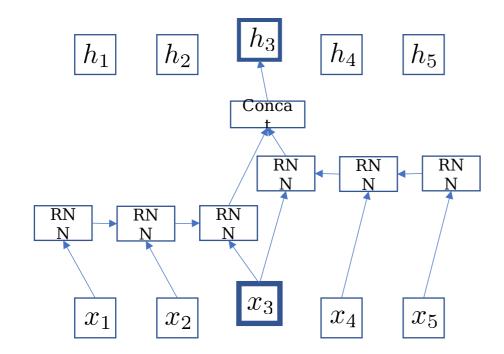

- Supervised learning: T input-output training pairs per sentence
 - Input: the entire source sentence and the preceding target tokens
 - Output: the next token

Decoder - Conditional Language Modelling

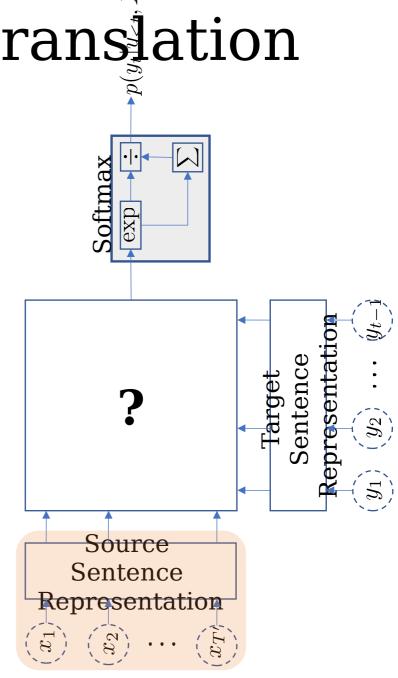

• Conditional Language mod (**M1***) g= $\prod_{t=1}^{t} p(y_t|y_{< t}, X)$

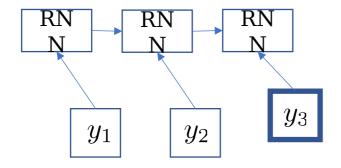

- 1. Source sentence representation
 - A stack of bidirectional RNN's

• The extracted vector at each location is a **context-dependent vector representation**.

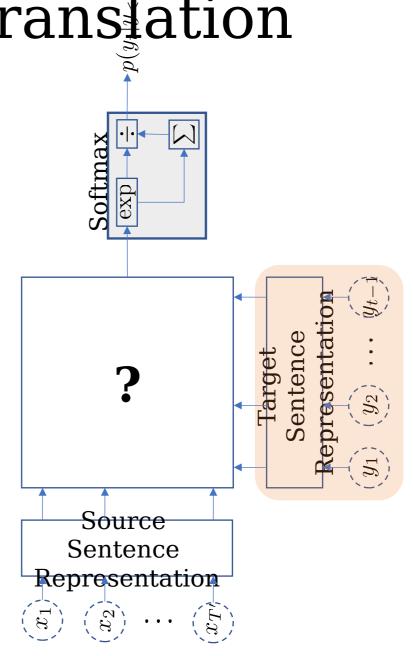

- 2. Target prefix representation
 - A unidirectional recurrent network

• Compression of the target prefix $z_t = RNN_{\text{decoder}}(z_{t-1}, y_{t-1})$

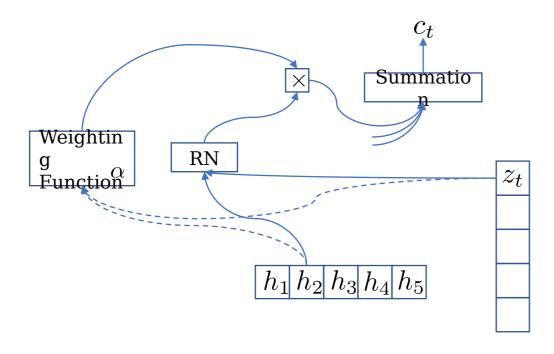

• Summarizes what has been translated so far

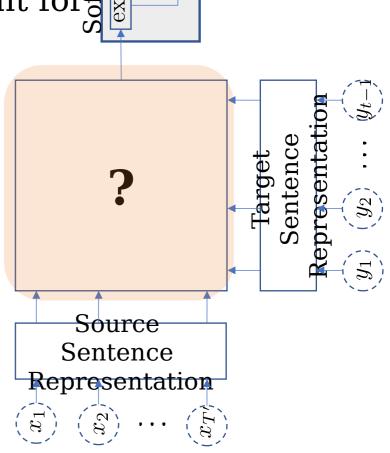

3. Attention mechanism

• Which part of the source sentence is relevant for predicting the next target token?

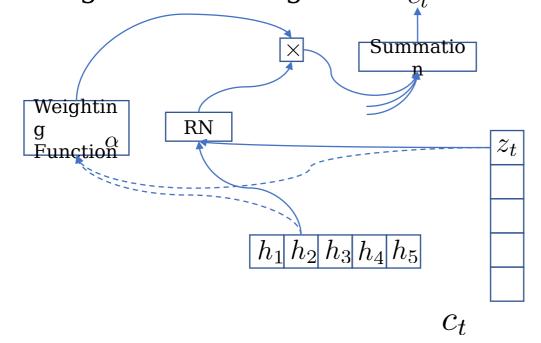

• Recall self-attention from Lecture 2

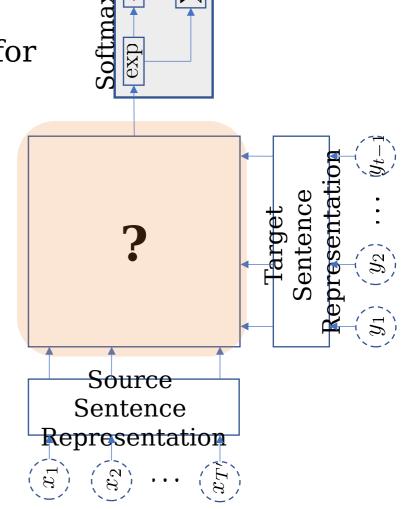

3. Attention mechanism

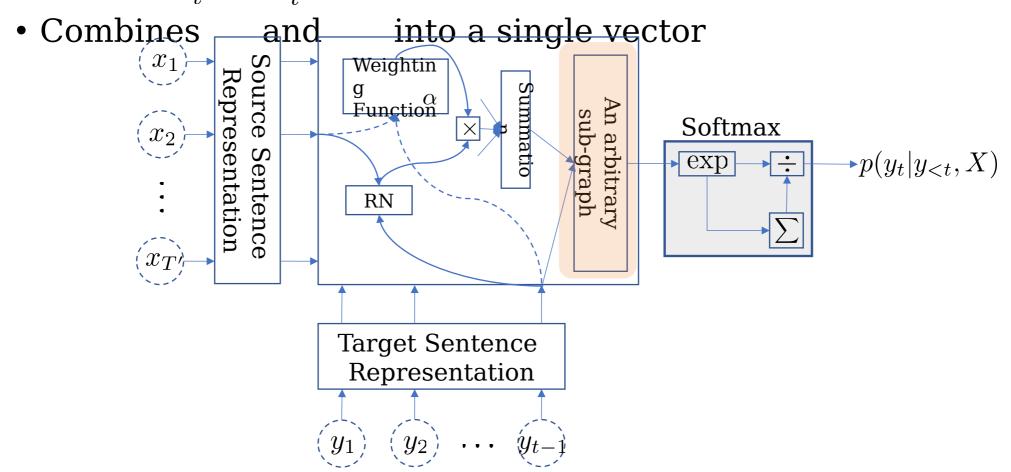

• Which part of the source sentence is relevant for predicting the next target token?

• Time-dependent source context vector

4. Fuse the source context vector and target prefix vector z_t c_t

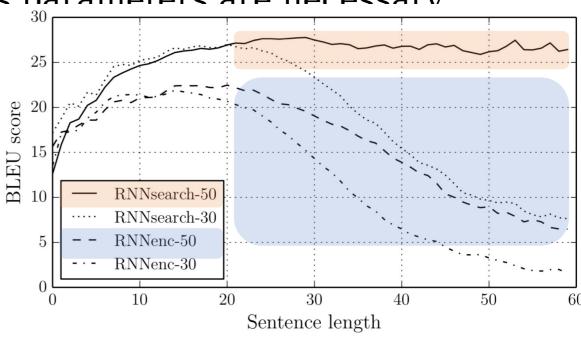

- Conceptual process
 - 1. Encode: read the entire source sentence to know what to translate
 - 2. Attention: at each step, decide which source token(s) to translate next
 - 3. Decode: based on what has been translated and what need to be translated, predict the next target token.
 - 4. Repeat 2-3 until the <end-of-sentence> special token is generated.

- The model is not pressured to compress the entire source sentence into a single, fixed-size vector:
 - Greatly improves the translation quality, especially of long sentences.

• Much more efficient: less parameters are necessary

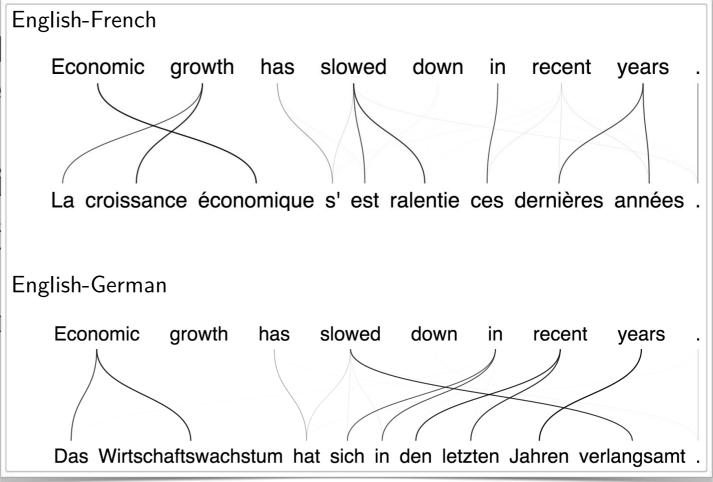

• Bahdanau et al. [2015] for the first time the matranslation purely base neural networks could good as then-state-of-thalternatives (e.g., PBM')

- **Source**: An admitting privilege is the right of a doctor to admit a patient to a hospital or a medical centre <u>to</u> carry out a diagnosis or a procedure, based on his status as a health care worker at a hospital.
- When collapsed: Un privilège d'admission est le droit d'un médecin de reconnaître un patient à l'hôpital ou un centre médical <u>d'un diagnostic ou de prendre un diagnostic en fonction de son état de santé.</u>

In practice,

- Many excellent open-source packages exist:
 - Marian-NMT https://marian-nmt.github.io/
 - Compute backend: C++
 - Maximal efficiency
 - Supported by Microsoft Translate
 - FairSeq https://github.com/facebookresearch/fairseq
 - Compute backend: PyTorch
 - Supported by Facebook AI Research
 - Nematus https://github.com/EdinburghNLP/nematus
 - Compute backend: TensorFlow (originally Theano)
 - Supported by U. Edinburgh and U. Zurich (Rico Sennrich)

In practice,

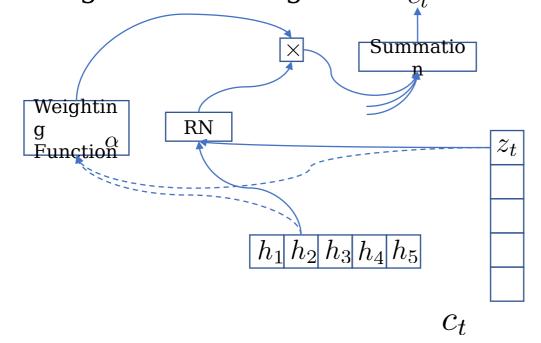

- Many new architectures are being proposed constantly
- Convolutional sequence-to-sequence models [Gehring et al., 2017]
 - Encoder: CNN-based sentence representation
 - Decoder: CNN-based conditional language model
- Transformers [Vaswani et al., 2017]
 - Encoder: Self-attention based sentence representation
 - Decoder: Self-attention based conditional language model
- It has been five years only, and a long road lies ahead...

Attention Mechanism

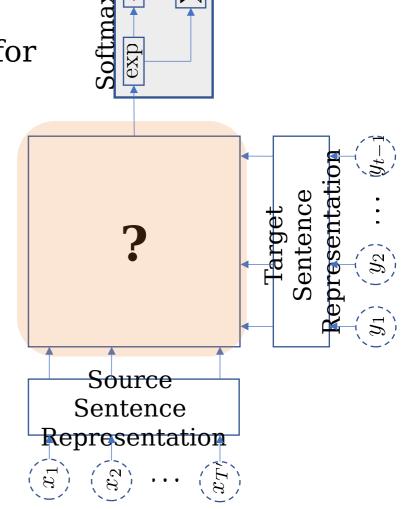

Delving deeper into the attention mechanism

3. Attention mechanism

• Which part of the source sentence is relevant for predicting the next target token?

• Time-dependent source context vector

Gated recurrent units to attention

• A key idea behind LSTM and GRU is the additive update $h_t = u_t \odot h_{t-1} + (1 - u_t) \odot \tilde{h}_t$, where $\tilde{h}_t = f(x_t, h_{t-1})$

• This additive update creates linear short-cut connections

Side-note: gated recurrent units to attention

• What are these shortcuts? h_{t+N}

• When unrolled, it's a weighted combination of all previous hidden vectors:

$$h_{t} = u_{t} \odot h_{t-1} + (1 - u_{t}) \odot \tilde{h}_{t},$$

$$= u_{t} \odot (u_{t-1} \odot h_{t-2} + (1 - u_{t-1}) \odot \tilde{h}_{t-1}) + (1 - u_{t}) \odot \tilde{h}_{t},$$

$$= u_{t} \odot (u_{t-1} \odot (u_{t-2} \odot h_{t-3} + (1 - u_{t-2}) \odot \tilde{h}_{t-2}) + (1 - u_{t-1}) \odot \tilde{h}_{t-1}) + (1 - u_{t}) \odot \tilde{h}_{t},$$

$$\vdots$$

$$= \sum_{i=1}^{t} \left(\prod_{j=i}^{t-i+1} u_{j} \right) \left(\prod_{k=1}^{i-1} (1 - u_{k}) \right) \tilde{h}_{i}$$

Gated recurrent units to causal attention

- 1. Can we "free" these dependent weights: $\begin{pmatrix} h_t = \sum_{j=i}^t \begin{pmatrix} \prod_{j=i}^{t-i+1} u_j \end{pmatrix} \begin{pmatrix} \prod_{k=1}^{i-1} (1-u_k) \end{pmatrix} \tilde{h}_i$
- 2. Can we "free" candidate vectors?
- 3. Can we separate keys and values? $\sum_{i=1}^{n} \alpha_i \tilde{h}_i$, where $\alpha_i \propto \exp(\operatorname{ATT}(\tilde{h}_i, x_t))$ 1
- 4. Can we have multiple attention heads?

$$h_t = \sum_{i=1}^{\infty} \alpha_i f(x_i), \text{ where } \alpha_i \propto \exp(\text{ATT}(f(x_i), x_t))$$
 2

$$h_t = \sum_{i=1}^t \alpha_i V(f(x_i)), \text{ where } \alpha_i \propto \exp(\text{ATT}(K(f(x_i)), Q(x_t)))$$
 3

$$h_t = [h_t^1; \dots; h_t^K], \text{ where } h_t^k = \sum_{i=1}^t \alpha_i^k V^k(f(x_i)), \text{ and } \alpha_i^k \propto \exp(\operatorname{ATT}(K^k(f(x_i)), Q^k(f(x_t))))$$

Gated recurrent units to non-causal attention

1. Look at the entire input sequence

$$h_t = [h_t^1; \dots; h_t^K], \text{ where } h_t^k = \sum_{i=1}^T \alpha_i^k V^k(f(x_i)), \text{ and } \alpha_i^k \propto \exp(\operatorname{ATT}(K^k(f(x_i)), Q^k(f(x_t))))$$

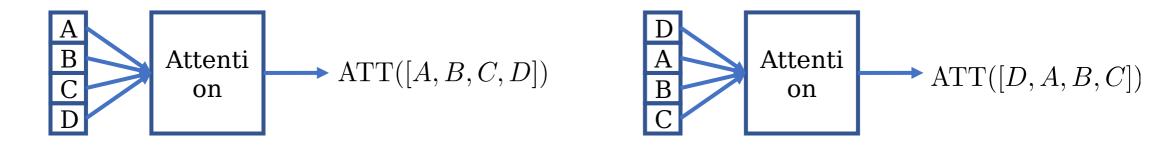

2. Give the sense of positions

$$h_t = [h_t^1; \dots; h_t^K],$$
where
$$h_t^k = \sum_{i=1}^T \alpha_i^k V^k(f(x_i) + p(i)),$$

$$\alpha_i^k \propto \exp(\text{ATT}(K^k(f(x_i) + p(i)), Q^k(f(x_t) + p(i))))$$

Non-causal attention and positional embedding

• Attention is position-invariant, C, D]) = ATT([D, A, B, C])

- Add position-specific vectors: positional embedding
 - Learned positional embedding [Sukhbataar et al., 2016]
 - Sinusoidal positional embedding [Vaswani et al., 2017]

Nonlinear Attention

- Attention is inherently linear, b/c it is a weighted sum of input vectors
 - *f* is often an identity function. *p* does not depend on the input.
 - *V* is often a linear traffsformation. $h_t^k = \sum_{i=1}^k \alpha_i^k V^k(f(x_i) + p(i))$
- A post-attention nonlinear layer
 - *g* is a feedforward neural network and applied to each time
 - step independently. For higher efficiency, \overline{g} may tapply to each head independently as well

Full self-attention layer

$$h_t = g([h_t^1; \dots; h_t^K]),$$

where

$$h_t^k = \sum_{i=1}^T \alpha_i^k V^k (f(x_i) + p(i)),$$

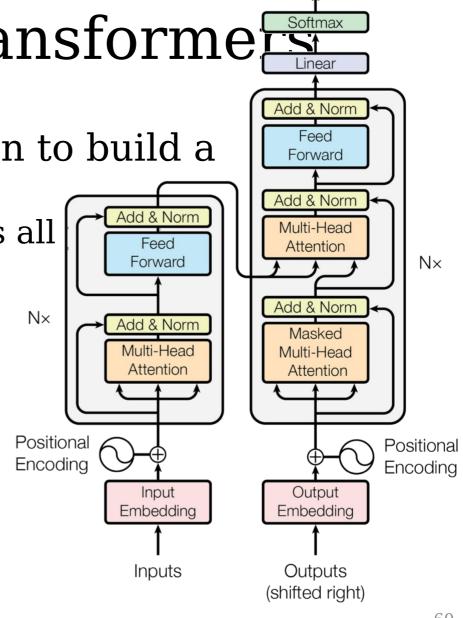

$$\alpha_i^k \propto \exp(\operatorname{ATT}(K^k(f(x_i) + p(i)), Q^k(f(x_t) + p(i))))$$

Parametrization - Transforme

• Stack multiple layers of attention to build a transformer

• Vaswani et al. [2017] - Attention is all

- A transformer block consists of
 - 1. Multi-headed attention
 - 2. Residual connection
 - 3. Feedforward layer
 - 4. Point-wise nonlinearity
 - 5. Residual connection
 - 6. (Layer) normalization

Output Probabilities

60
